Developmental Biology of the Sea Urchin Embryo discusses both structural and experimental observations on the morphological and metabolic aspects of sea urchin embryology. It is organized into two major parts, designated morphogenesis and related problems and metabolism. These parts encompass 12 chapters that cover the role of sea urchin embryology in developmental biology and the advantages and limitations of using sea urchin embryo in the study of developmental problems.

The simplicity of their early development, and the ease of experimentally perturbing this development, provides an excellent platform for mechanistic studies of cell specification and morphogenesis. As a result, echinoderms have contributed significantly to our understanding of many developmental mechanisms, including those that govern the structure and design ...

The sea urchin embryo has long been used as a model organism to address many questions in developmental biology. There are a number of important features that make the sea urchin an ideal system. The straightforward artificial spawning, fertilization and rearing, and embryo optical transparency make this organism a great resource.

The most common and ancestral mode of reproduction is indirect (planktotrophic) development, during which the fertilized egg is transformed into a swimming, feeding larva known as a pluteus larva, or echinopluteus. This embryonic phase of development is quite short (1-4 days, depending on the species and temperature).

1. The osmotic theory suggests that ions and proteins are secreted into the blastocoel by the blastomeres and this results in a pressure buildup due to the osmotic flow of water. This pressure would then be responsible for aligning the axis mitosis of the blastomeres and the enlargement of the blastocoel. 2.
